

ignores geometry

The same intuition holds for interpolation

(e)

Recall from last time:

- Warm-up: simple dataset with structure
- First attempt: “normal” (euclidean) averaging
- This **ignores geometry!**
- Is there a better way?
- OT can average in a meaningful way
- **The same intuition holds for interpolation**

Example: Dirac $\rightarrow$ Dirac

$$\alpha = \delta_{x_0}, \beta = \delta_{x_1}$$

Displacement interpolation =
'normal' (linear) interpolation

$$\rho_t = \delta_{(1-t)x_0 + tx_1}$$

Mixture interpolation = splits diracs

$$\rho_t = (1-t)\delta_{x_0} + t\delta_{x_1}$$
